Registered charity number 1097899

The Energy Institute (EI) is the chartered professional membership body for the energy industry, supporting over 20 000 individuals working in or studying energy and 250 energy companies worldwide. The EI provides learning and networking opportunities to support professional development, as well as professional recognition and technical and scientific knowledge resources on energy in all its forms and applications.

The EI's purpose is to develop and disseminate knowledge, skills and good practice towards a safe, secure and sustainable energy system. In fulfilling this mission, the EI addresses the depth and breadth of the energy sector, from fuels and fuels distribution to health and safety, sustainability and the environment. It also informs policy by providing a platform for debate and scientifically-sound information on energy issues.

The EI is licensed by:

- the Engineering Council to award Chartered, Incorporated and Engineering Technician status;
- the Society for the Environment to award Chartered Environmentalist status.

It also offers its own Chartered Energy Engineer, Chartered Petroleum Engineer and Chartered Energy Manager titles.

A registered charity, the EI serves society with independence, professionalism and a wealth of expertise in all energy matters.

This publication has been produced as a result of work carried out within the Technical Team of the EI, funded by the EI's Technical Partners. The EI's Technical Work Programme provides industry with cost-effective, value-adding knowledge on key current and future issues affecting those operating in the energy sector, both in the UK and internationally.

# 1 EXECUTIVE SUMMARY

This G+ Safe by Design workshop was focused on the issues associated with hydraulic torqueing and tensioning on the main flange connections and the associated large fasteners and tooling. The workshop, comprising several data gathering and data analysis activities, was held in London on 5 March 2019. The workshop format was developed to explore hydraulic torqueing and tensioning system issues with a focus on the Safe by Design (SbD) principles.

Across the workshop, many common and interrelated issues and associated recommendations were identified, and these are shown in 1.1.

## 1.1 RECOMMENDATIONS

- Industry-wide knowledge sharing of torqueing/tensioning issues encountered, how these were solved, what works and what doesn't, could help to improve the current operation and maintenance (O&M) activities and future wind turbine generator (WTG) designs, both in terms of health and safety (H&S) and cost. Additionally, the development of a guidance document using the information obtained from these issues and consideration of good practices in other industries could be useful.
- WTGs and transition pieces (TP)s may not always seem to be fully considered as 'places of work' during the design process. Several ergonomic hazards were identified that could be designed out of future WTGs and TPs. Therefore, it could be beneficial to facilitate further engagement of original equipment manufacturers (OEM)s, owners and operators and technicians to share feedback from issues/accidents attributed to these design features.
- Musculoskeletal disorders caused by manual handling and use of the equipment, often in restricted space, were identified as a significant issue. This issue is not unique to hydraulic torqueing/tensioning and is a challenge facing the industry. The G+ is about to publish a case study based on the analysis of reducing manual handling and ergonomics related incidents in the offshore wind industry which will be followed by a guidance document for manual handling. In addition to that, a G+ SbD workshop, or other initiative exploring this topic more fully and sharing the output could be valuable.
- During the safe by design workshops, bolt torqueing and tensioning tool manufacturers described improved or innovative products which offer the potential to reduce hazards, either associated with manual handling, ergonomics, transport or positioning of the tools. It is recommended that methods to improve the visibility of G+ member organisations and their procurement teams to these potential solutions are explored. It is suggested that having an understanding at the point where purchasing decisions are made of how a slightly more expensive product may reduce risks, and the value that these offer, has the potential to lead to safer projects in future.

- During the safe by design workshops, it was identified and highlighted that improved quality assurance/quality control on bolted connections drastically reduces the exposure due to reduced problems/interventions associated with the bolting activities. Various solutions were identified including, but not limited to:
  - More bolting and testing in prefabrication (rather than offshore).
  - Introduction of torque testing techniques (ultrasonic testing).
  - Smart bolts (with tension/torque ID).
- Innovations such as alternative power (electric rather than hydraulic), remote control, or robotic solutions may require demonstration to build track record and industry confidence. The opportunity to facilitate trials or demonstrations of new technology should be explored. For example, do any G+ member organisations have an onshore mock-up of foundations which could be used as a demonstration environment? Are any test facilities available, if not what capabilities should they have, and which organisations could develop them? Related to this, mechanisms enabling the experience of early adopters to be shared would be valuable and should be explored.
- Task-specific training could be very useful to ensure competency during operations. The G+ could review the current training landscape to determine if there are any opportunities for improvement based on the outputs of this workshop, including items such as roles and responsibilities, and competency tracking.
- Tracking tool use, maintenance and calibration was identified as an area of opportunity to reduce these factors contributing to tool failure. Incorporating the need for this tracking to be built into future tool designs could be of benefit for the industry. The G+ could gather insight from the industry and publish a set of recommended requirements.
- The G+ could perform a cost-benefit analysis of permanently storing spare parts and/or tools for bolt tensioning and torqueing on WTG (i.e. the benefit of being more able to perform work/less down-time versus additional inspections and maintenance offshore).

## **2 BACKGROUND AND INTRODUCTION**

### **2.1 BACKGROUND**

The G+ Global Offshore Wind Health and Safety Organisation (G+) comprises the world's largest offshore wind developers who have come together to form a group that places health and safety at the forefront of all offshore wind activity and development. The primary aim of the G+ is to create and deliver world class health and safety performance across all its activities in the offshore wind industry. The G+ has partnered with the Energy Institute (EI) to develop materials including good practice guidelines to improve health and safety performance. Through sharing and analysis of incident data provided by G+ member companies, an evidence-based understanding of the risks encountered during the development, construction and operational phases of a wind farm project has been developed. This information has been used to identify the health and safety risk profile for the offshore wind industry.

In 2014, the Crown Estate asked the G+ to take over the running and delivery of their SbD workshops. The Crown Estate had run a number of these previously covering topics such as diving operations, lifting operations, wind turbine design and installation and the safe optimisation of marine operations.

By bringing the Safe by Design workshops into the G+ work programme, the G+ aims to explore industry operations and technologies with a focus on SbD principles. The G+ workshops examine the current design controls relating to a topic, discuss where current design has potentially failed, identify opportunities for improvement and then seek to demonstrate the potential risk reduction to be gained from these new ways of thinking and operating.

To date, seven workshops have been held under the auspices of the G+, covering: marine transfer/access systems; escape from a nacelle in the event of a fire; lifting operations; service lifts; davit cranes; WTG access/egress, and WTG access below the airtight deck. The outputs from six of these workshops have been made available in reports which can be downloaded from the G+ website, to be used as a reference by the industry.

<https://www.gplusoffshorewind.com/work-programme/workshops>

### **2.2 INTRODUCTION**

From data analysis and feedback received by the G+, hydraulic torqueing and tensioning was identified as an area that should receive additional focus. Therefore, under the direction of the G+ Focal Group, a SbD workshop on hydraulic torqueing and tensioning systems was held on 5 March 2019 in London, UK.

The outputs from this workshop are documented in this report.

## 3 METHOD/ATTENDANCE/AGENDA

### 3.1 METHOD

A one-day workshop was held on 5 March 2019 in London, bringing together stakeholders from across the industry to consider the issues associated with hydraulic torqueing and tensioning in a WTG in the offshore environment. This was focused on the large structural flange connections, but many of the issues and recommendations made are common to torqueing and tensioning throughout a WTG. After opening remarks from Marcus Peters, Head of HSSE, Offshore Technologies, Wind Construction & New Markets, E.ON Climate & Renewables GmbH, two scene-setting presentations were delivered on 'Typical bolted connections' and 'MP/TP bolting operations'. To conclude the opening session, and allow a smooth transition to the workshop exercises, a short overview of these was provided, as shown.

#### Exercise 1 – Hazard identification (HAZID)

- Brainstorming techniques were used to identify the hazards associated with hydraulic torqueing and tensioning systems.
- Three main areas were covered, with each of the three workgroups covering one of these areas:
  - Storage, transportation and handling.
  - Operation of the tools.
  - Tool maintenance.
- This was followed by identification of the main hazards associated with these activities. The most significant activities and hazards were explored further in Exercise 2.

#### Exercise 2 – Hazard risk analysis (Bow tie)

- Bow tie analysis of the most significant hazards identified in stage 1 was conducted.
- This involved selecting a top failure event from the hazards analysed and identifying the threats, consequences, controls and mitigations associated with the hazard/top failure event.

#### Exercise 3 – Hierarchy of control

- In the final exercise, the most significant hazards were analysed further with respect to the hierarchy of control.
- This resulted in suggestions for how each of these activities/hazards could be eliminated or substituted.

The attendees were split into three groups and participated in each of these exercises.

At the end of the day the initial findings and conclusions were presented to the attendees in a plenary session, before concluding the workshop.

Note – the full results and details of the workshop exercises are shown in Annex A of this report.

### 3.2 AGENDA

#### **Workshop opening remarks**

*Marcus Peters*, Head of HSSE, Offshore Technologies, Wind Construction & New Markets, E.ON Climate & Renewables GmbH

#### **G+ incident data** – what is the evidence telling us?

*Beate Hildenbrand*, Technical Manager – Offshore Wind, Energy Institute

#### **Typical bolted connections**

*George Walker*, Associate Engineer, Arup

#### **MP/TP bolting operations**

*Edward Gilhead*, Foundation Engineer, E.ON Climate & Renewables GmbH

#### **Workshop exercises introduction and overview**

*Gordon Stewart*, SHEQ Manager, Offshore Renewable Energy Catapult

#### **Workshop exercises**

Each exercise led by a Catapult facilitator; *Owen Murphy, Craig Stout and Roberts Proskovics*

**Plenary session** – Presentations on key findings/outputs from workshop

#### **Closing remarks**

*Marcus Peters*, Head of HSSE, Offshore Technologies, Wind Construction & New Markets, E.ON Climate & Renewables GmbH

Tony Lyon	Xceco

## ANNEX A

### DETAILED WORKSHOP NOTES

#### A.1 WORKSHOP EXERCISE 1: HAZARD IDENTIFICATION (HAZID)

##### A.1.1 Purpose

The purpose of this exercise was to identify activities and hazards associated with the storage, transport and handling of tools, use of tools, and maintenance of tools for hydraulic torqueing or tensioning. These tools are used for structural bolted connections in offshore wind turbine substructures. The hazards were discussed and participants in each of the work groups described current control measures which were in place to control the hazards. Potential solutions or improvement ideas and behavioural factors were also discussed. The hazards identified in this exercise were prioritised by the work groups and the highest priority hazards were taken forward for further analysis in the bow tie sessions which followed.

##### A.1.2 Outputs

###### A.1.2.1 Evidence

See Tables A.1 – A.3 for the results of the HAZID exercises across the three areas as described in A.1.1.

**Table A.1: Storage transport and handling of tools hazard identification**

Hazard	Current control measures	Potential solutions/ improvement ideas	Unsafe acts/ behavioural aspects
Defects induced by inadequate or inappropriate storage	<ul style="list-style-type: none"> <li>– Clearly defined and delegated responsibilities</li> <li>– Equipment testing and calibration</li> <li>– Pre-use checks</li> </ul>	<ul style="list-style-type: none"> <li>– Purpose designed transport bags or cases</li> <li>– Dedicated storage locations</li> <li>– Defined 'owners' for equipment</li> </ul>	<ul style="list-style-type: none"> <li>– Complacency</li> <li>– Poor culture</li> <li>– 'someone else's job'</li> <li>– No time allocated for teams to store equipment properly</li> </ul>
Omissions caused by lack of ownership (storage, during transfer and at point of work)	<ul style="list-style-type: none"> <li>– Clearly defined and delegated responsibilities</li> <li>– Pre-use checks</li> </ul>	<ul style="list-style-type: none"> <li>– Purpose designed transport bags or cases</li> <li>– Smart lifting bags</li> <li>– Defined 'owners' for each stage in the process</li> <li>– Direct supervision</li> </ul>	<ul style="list-style-type: none"> <li>– Complacency</li> <li>– Poor culture</li> <li>– 'Someone else's job'</li> <li>– No time allocated for teams to clean or maintain tools after use or transport</li> </ul>

#### A.1.2.2 Analysis and findings

The three hazard identification exercises conducted by the three separate working groups focused on a specific phase of activities. These were:

1. Storage, transport and handling of tools.
2. Use of tools.
3. Maintenance of tools.

The groups each identified a wide range of potential hazards which have been summarised in Tables A1 to A3. It is noteworthy that despite the focus on different phases of activities, and the fact that workshop discussions occurred simultaneously without any conferring from one group to the other, that some hazards were identified by all groups. These represent consistent themes of the potential hazards associated with hydraulic bolt torqueing and tensioning equipment for substructure bolted connections. They have been summarised in A.1.2.2.1 to A.1.2.2.3.

##### A.1.2.2.1 Manual handling and ergonomics

The tools and equipment associated with the tensioning and torqueing of large structural bolts are by necessity large and powerful. In introductory presentations, M72 bolts were described as weighing around 20 kg without nuts or washers. The groups discussed how bolts themselves were often already on the limits of acceptable masses for manual handling, typical sizes starting at M56 with M72 considered common, and that generally tools and equipment were heavier still (Figure A.1 and Figure A.2). It was also apparent that with a continuing upwards trend in sizes of offshore wind turbines, the number and masses of these fasteners is likely to continue to increase.

The bulky equipment required to perform torqueing or tensioning of these large fasteners needs to go through a variety of transport and handling tasks to complete the tensioning/ torqueing work. It will be handled in stores both as goods in and good out. Some or all this movement may avoid manual handling through use of forklifts, pallet trucks or overhead cranes, depending on the facility. It will then be transferred to and from a vessel, onto and off a turbine/transition piece and then lowered/raised to the lower decks/working platforms. The final step in this journey is likely to utilise non-permanent lifting equipment or systems which are likely to be rigged and removed specifically for the purpose of transporting equipment to and from the lower working platforms in the foundation.

The tools themselves may not have been designed for the specific handling and transportation necessities of the offshore wind industry. The theme of manual handling and ergonomic injuries was discussed in each workshop. Because of the variety of transport and handling methods used, it was suggested that packaging and lifting equipment may not always be of the optimum design for the task. Equipment may commonly be decanted to/from generic lifting bags which were well suited to lifting from a davit crane but may not protect the equipment from salt spray during vessel transit, and did not prevent the tools and equipment moving around, meaning that impact damage of tools which are loose in lifting bags was possible.

### **Potential improvements**

- The sourcing or design of more appropriate tools and transport cases/bags. Ideally, these solutions should be afforded the opportunity to incorporate the direct feedback of user's experience.
- When considering further mitigations to manual handling hazards, the use of mechanical aids was also discussed. These could be powered or purely mechanical systems such as levels, wheels, springs and rollers which enabled the tools to be positioned, used and moved without significant physical exertion.
- Other potential methods of reducing manual handling and ergonomics hazards included improving the design of the working environment itself to reduce ergonomic challenges such as reach, headroom or otherwise restricted working areas. The trade-off between a structural design which was cost-efficient to manufacture and one which included a working environment which minimised ergonomic hazards was discussed. It was felt that because of a relatively low frequency of access across the windfarm lifetime it was possible that ergonomic features of the lower desk working areas were overlooked or at least not given much priority in design optimisation.
- The reduction of, or means to monitor or control, noise was also cited as a potential way of reducing hazards. Noise has the potential to contribute to hazards in two distinct categories. Noise can be hazardous and potentially damaging to a person's hearing. Further hazards related to difficult communications may also be induced when using powerful equipment in a noisy environment.

Figure A.1 is an extract from Annex A of BS EN ISO 4762:2004 which provides approximate masses. Note that fasteners of relevance to the subject matter discussed in these workshops tend to go beyond the lower right-hand side of this table, and hence will be heavier still. Nonetheless, this figure provides an insight into some likely masses for fasteners of this type.

Figure A.1: Typical bolt masses, credit BS EN ISO 4762:2004 Annex A

Figure A.2 is an extract from guidance on manual handling. Whilst limits are not the only element of a robust approach to manual handling hazard identification, and there is much more detail to the guidance and best practice, the diagram does provide some useful context. Firstly, it highlights that lifting fasteners with masses of 20 kg by hand is likely to be acceptable over a very small range of movement, and even then, likely by men only. Further, it illustrates how, when working in a relatively constrained space where the range of working heights may be limited by the physical design of the structure itself, a reduced limit is recommended as the distance from the ideal lifting location increases.

Figure A.2: Manual handling, available at: <https://www.internationalworkplace.com/az-guides/manual-handling-guide>

#### A.1.2.2.2 Uncontrolled release of energy

Tools and equipment used for torqueing and tensioning of large structural bolts are almost always hydraulically powered. Hazards associated with this source of power, such as failures of hoses or couplings which can release harmful jets of fluid, or the slip and trip hazard posed by smaller leaks were discussed.

Arguably the most severe potential injury possible as a result of this type of release of energy was hydraulic injection injury, which was cited as a consistent cause of concern. This type of injury will almost always require urgent medical treatment by surgical professionals, and the increased time to evacuate a casualty who may be working below the airtight deck offshore was described as having the potential to increase the severity of injuries.

The groups described through anecdotal evidence that at present, minor leaks when using hydraulic tooling were almost inevitable. It was felt that this may be because equipment is either badly made and/or badly specified for the task or environment. However, often failures resulting in an uncontrolled release of energy were likely to be caused by misuse or harsh treatment of equipment, or because tools were not looked after and had to withstand rough treatment when in transport and in use.

The uncontrolled release of energy could also include mechanical failure or the ejection of parts. This was described as having been experienced by some members of some of the discussion groups. Hazards identified by failures such as the fracture when under tension of hydraulic tensioning heads or of bolts themselves included impact of parts or debris moving at high velocity with people, with the potential to cause severe injury. The need for adequate separation distances between energised parts and teams conducting the work was discussed as a potential mitigation. However, physical space can be at a premium when working inside the foundation, or tools may require direct visual observation when in operation, which can mean that people are required to be in closer proximity to these energised systems than would perhaps be considered ideal.

#### A.1.2.2.3 Attitude, ownership and culture

All the groups discussed either a lack of clarity or a lack of ownership or responsibility for the tools and equipment as a potential contributor to defects, resulting in failure of the equipment. Mechanical or hydraulic failure were cited as having the potential to release energy and cause injury. Defects induced by rough treatment, incorrect handling or misuse were described as having the potential to contribute defects which could make such failures more likely. It was clear that a range of people would handle and use the equipment, and that a relatively basic care or maintenance task such as cleaning may be missed as a large team may each assume it to be somebody else's responsibility. Allocation of tools, inventory and record keeping of tasks such as pre-use checks or basic maintenance were discussed areas with the potential to be improved. Participants described an uncertainty over who was responsible for the care, appropriate handling and use of tools, particularly when large projects comprise several teams and rely on a large amount of pooled equipment.

Participants in the working group also described the potential for improved designs of the tools themselves. For example, if equipment is bulky or difficult to move but does not have a carry handle it may be much easier to use hose fixings as a handle than trying to position only by hand. Often such misuse may take place with the best of intentions, or with the intent of working more quickly or more efficiently. It was thought unlikely that users were deliberately mistreating equipment to the extent that it would fail, but rather that designs could probably be improved if they incorporated the experience of front-line users.

#### A.1.2.2.4 Training, competence and verification

To be confident that those handling and using tools and equipment are likely to use it correctly a sufficient level of competence will be required. Workshop participants described a patchy landscape of training qualifications and experience which could be used to consider an individual sufficiently competent to conduct or supervise hydraulic torqueing or tensioning works. It was felt that there was potential for hazardous misuse of equipment, often with the best of intentions, arising from a lack of awareness or competence. Workshop participants described the generic nature of any training, and the differences between specific tools or tool manufacturers as potentially contributing to hazards. For example, if a user had received training using a particular type of tool from one manufacturer, they may then go on to use a completely different type with different controls in the future. It was felt that a user could also probably work for quite a long time with one particular system, for example if an installation campaign lasts for several months, giving good familiarity with a particular type of tools, which may lead to accidental misuse of different tools on subsequent projects.

#### **Potential improvements**

- A more robust scrutiny of training or experience, direct supervision or audit of the various phases of the work (transport of tools, use of tools and maintenance of tools) or potentially a review of what training syllabuses are relevant to this area.
- Some participants discussed, and were in favour of, formalising the training, and authorisations to be more specific about which users are permitted to conduct which task. For example, it was suggested that training could be structured around several levels. These levels would ensure that there was much clearer delineation of who was capable, competent and authorised to conduct various tasks. For illustration these levels could include: basic user; functional tester; light/in-field maintenance and workshop maintenance, all of which may require different skills and competence.
- The frequency of any refresher training and variance in approach from one project to the next were also mentioned and again it was suggested as potentially prudent to review these; anecdotes were provided which suggested that someone could be deemed to be competent when in fact their original training was provided several years ago and/or of relevance only to a particularly type or manufacturer of tools.

#### A.1.2.2.5 Procurement

All the work groups discussed the trade-off between quality and capability of tools and the overarching corporate requirement to procure for the lowest possible cost. In some cases, hazards associated with hydraulic tools could be eliminated or reduced by using more expensive systems, for example those which used either electric power supply and/or were equipped to enable remote control from a safe area. Other innovations which could add to the cost but reduce exposure to risk included mechanical lifting aids or roller systems which reduced or eliminated some of the manual handling requirements.

Related to procurement, it was evident that there was a variety of approaches to management of potential risks associated with the equipment by placing the risk either in-house or with suppliers or subcontractors. The ability to better manage risks and potential hazards arising by considering whether to purchase tools and equipment, to rent them or to source labour and equipment together from an experienced contractor was discussed. This could be viewed as a key decision that should be made at the start of the project. Interestingly there was no consensus on what the best approach was, each having pros and cons. It was noted that at times the lowest cost may not always be the best value; for example, more expensive tools may be more robust, fail less frequently or last longer. Similarly, risks could be reduced by engaging the manufacturer of the equipment to provide maintenance and spare parts.

### A.1.2.3 Recommendations and outputs

The following thoughts, considerations and recommendations were developed during Exercise 1. The refined report recommendations are shown in the Executive Summary in section 1.

- It is recommended that the G+ review the current training standards and syllabus(es) in this area considering the workshop outputs presented in this report. Specifically, it is recommended that consideration is given to:
  - Whether training is relevant to all tools and manufacturers currently used in the offshore wind industry.
  - Whether training content provides any delineation between operation and maintenance of the tools, and whether a separate or additional training scope, for example for workshop maintenance/stores persons, would be worthwhile.
  - What tool manufacturers' input has been used in the development of training standard(s).
  - Whether there is a risk that an individual may be deemed competent despite holding a training qualification which is either several years old, or which is relevant to equipment of a different type/manufacturer.
  - Whether training material covers the appropriate packing, transport and handling of the tools.
- It is recommended that consideration is given to circulating a safety bulletin or guidance note on the topic covered by this workshop. Specifically, this could include:
  - Link to this report summarising the SbD workshop.
  - Recommendation that the client in charge of bolt torqueing or tensioning work should clearly define which members of the team have which responsibilities and at which times. The aim of this clarification is to avoid situations where team members may see checks or maintenance tasks as somebody else's job.
- This document could also include some reminders of potential damage mechanisms and hazardous consequences which could arise following incorrect transport and handling of tools.
- It is recommended that mechanisms for site technicians to provide feedback of their direct experience to project design teams are investigated.
- It is recommended that the G+ good practice guidelines for manual handling are circulated to workshop participants and that the existence and relevance of these guidelines are communicated to project design and site teams.

## A.2 WORKSHOP EXERCISE 2: HAZARD RISK ANALYSIS – BOW TIE

### A.2.1 Purpose

The purpose of this exercise was to investigate a top failure event that could occur from a hazard being realised. The working groups were provided with a top failure event for one of the most significant hazards identified in Exercise 1. The groups brainstormed the threats (that can cause the failure event to happen), consequences (which can result from the failure event occurring) and the controls and mitigations. These details were captured on a wall-mounted bow tie template.

---

## A.2.2 Outputs

### A.2.2.1 Evidence

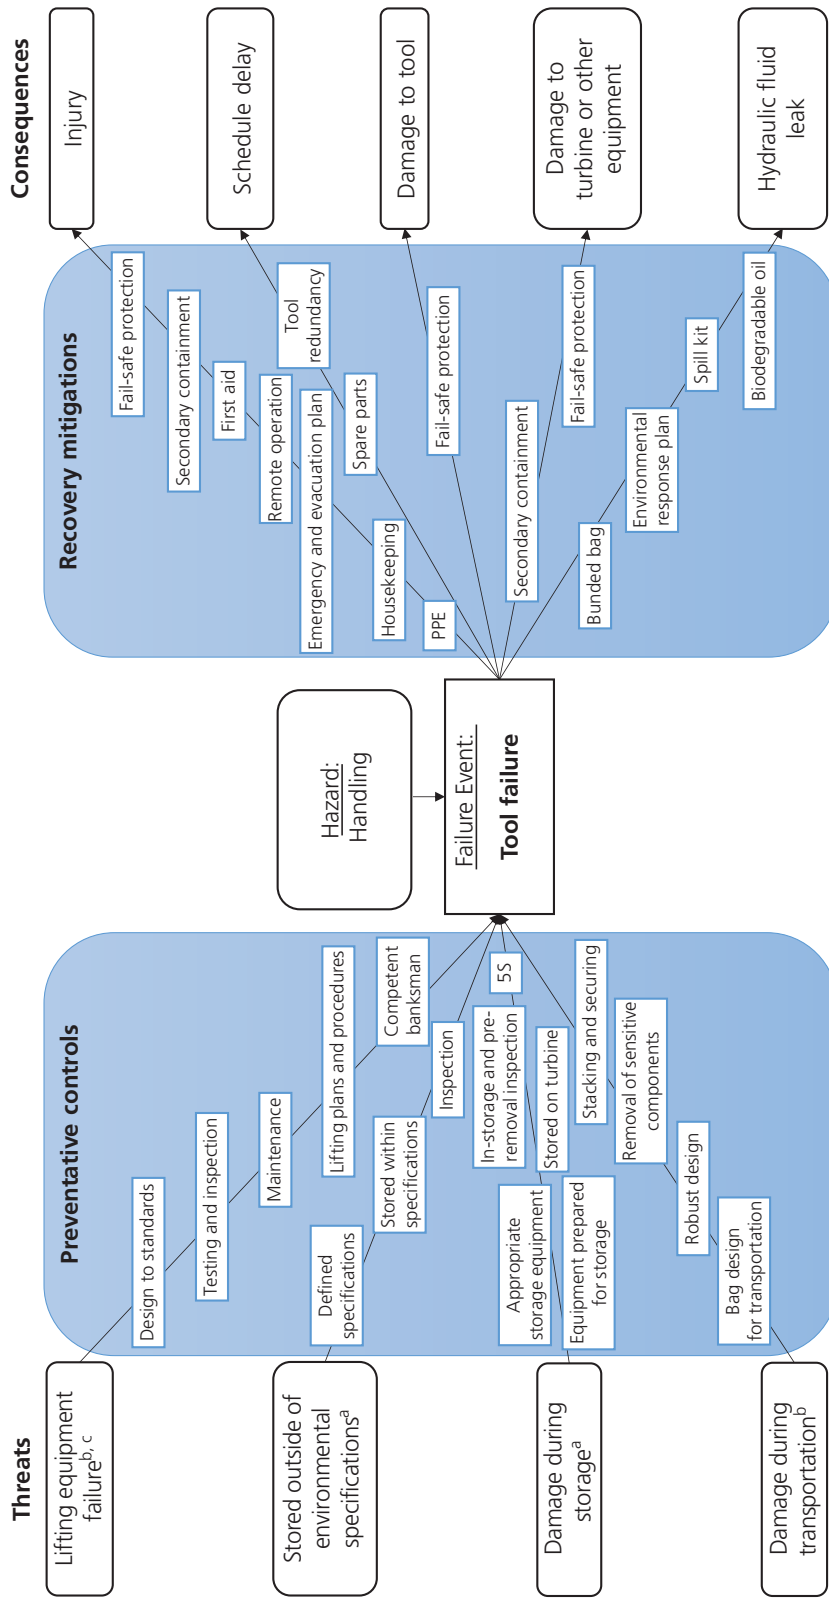

The three groups each analysed a different hazard and top failure event using the bow tie methodology, and each group completed a bow tie diagram.

Bow tie diagrams were created for the following:

- Area: Storage, transportation and handling. Hazard: Handling. Failure event: Tool failure.
- Area: Operation of the tools. Hazard: Operation of the tools. Failure event: Tool failure.
- Area: Tool maintenance. Hazard: Inadequate maintenance regime. Failure event: Release of high-pressure hydraulic fluid.

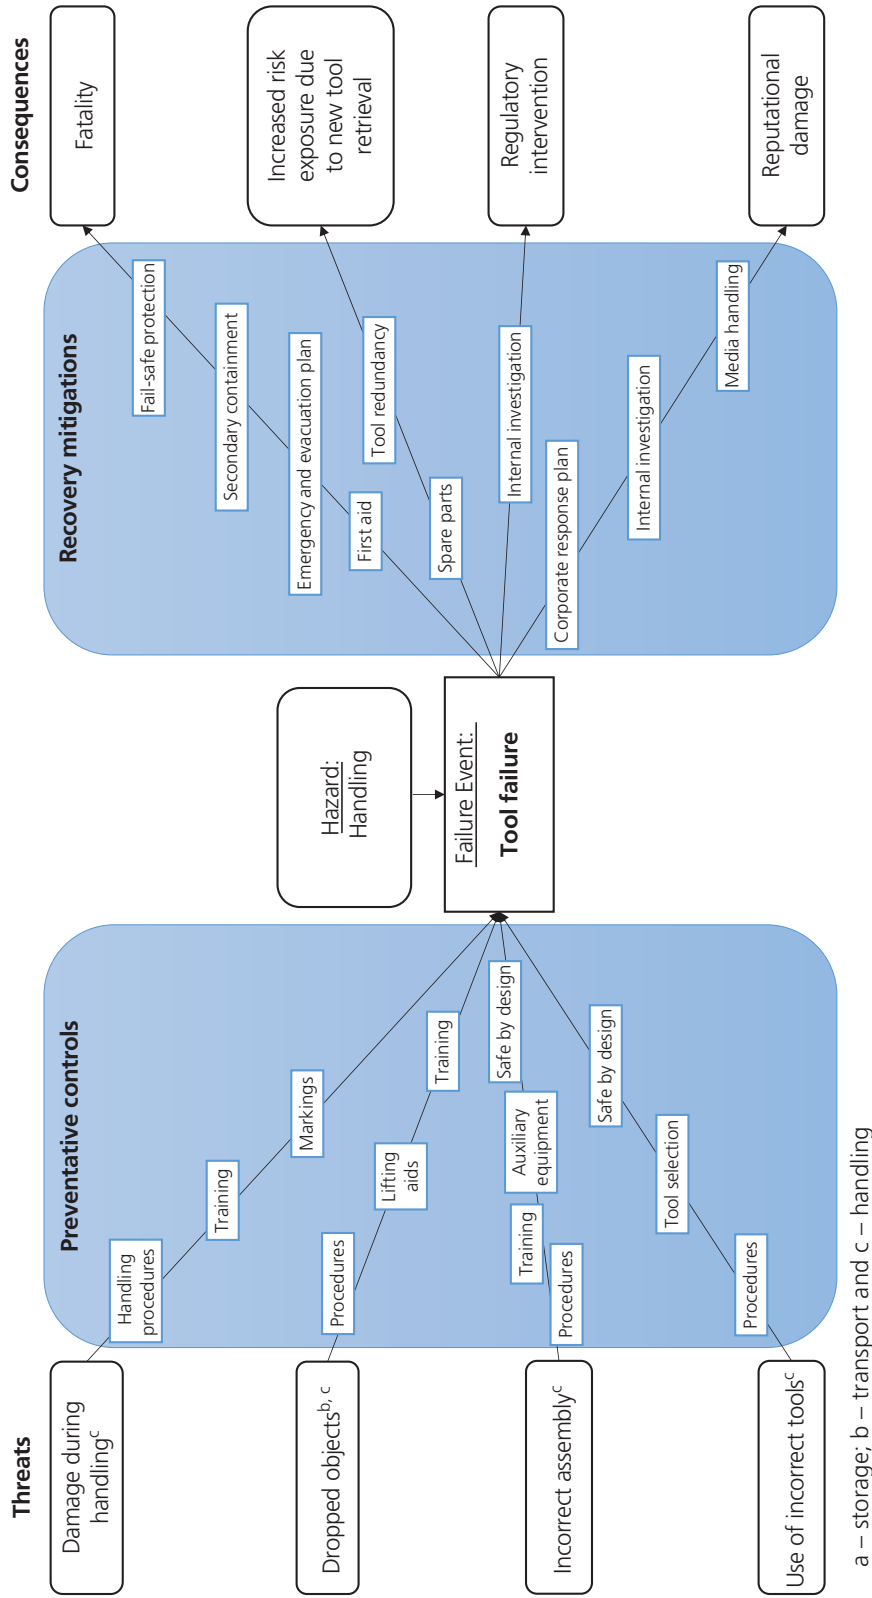

The bow tie diagrams are shown in Figures A.3 to A.8.

Note: For Figure A.5, Figure A.6 and Figure A.7, preventive control and recovery mitigation measures that are not associated with any specific threat and consequence (i.e. do not intersect threat to consequence path) are applicable to all threats and consequences, respectively.

a – storage; b – transport; c – handling and \* – indicates suggested improvements

Figure A.3: Tool failure in handling bow tie (a – storage; b – transport; c – handling) (1/2)

a – storage; b – transport and c – handling

Figure A.4: Tool failure in handling bow tie (a – storage; b – transport; c – handling) (2/2)

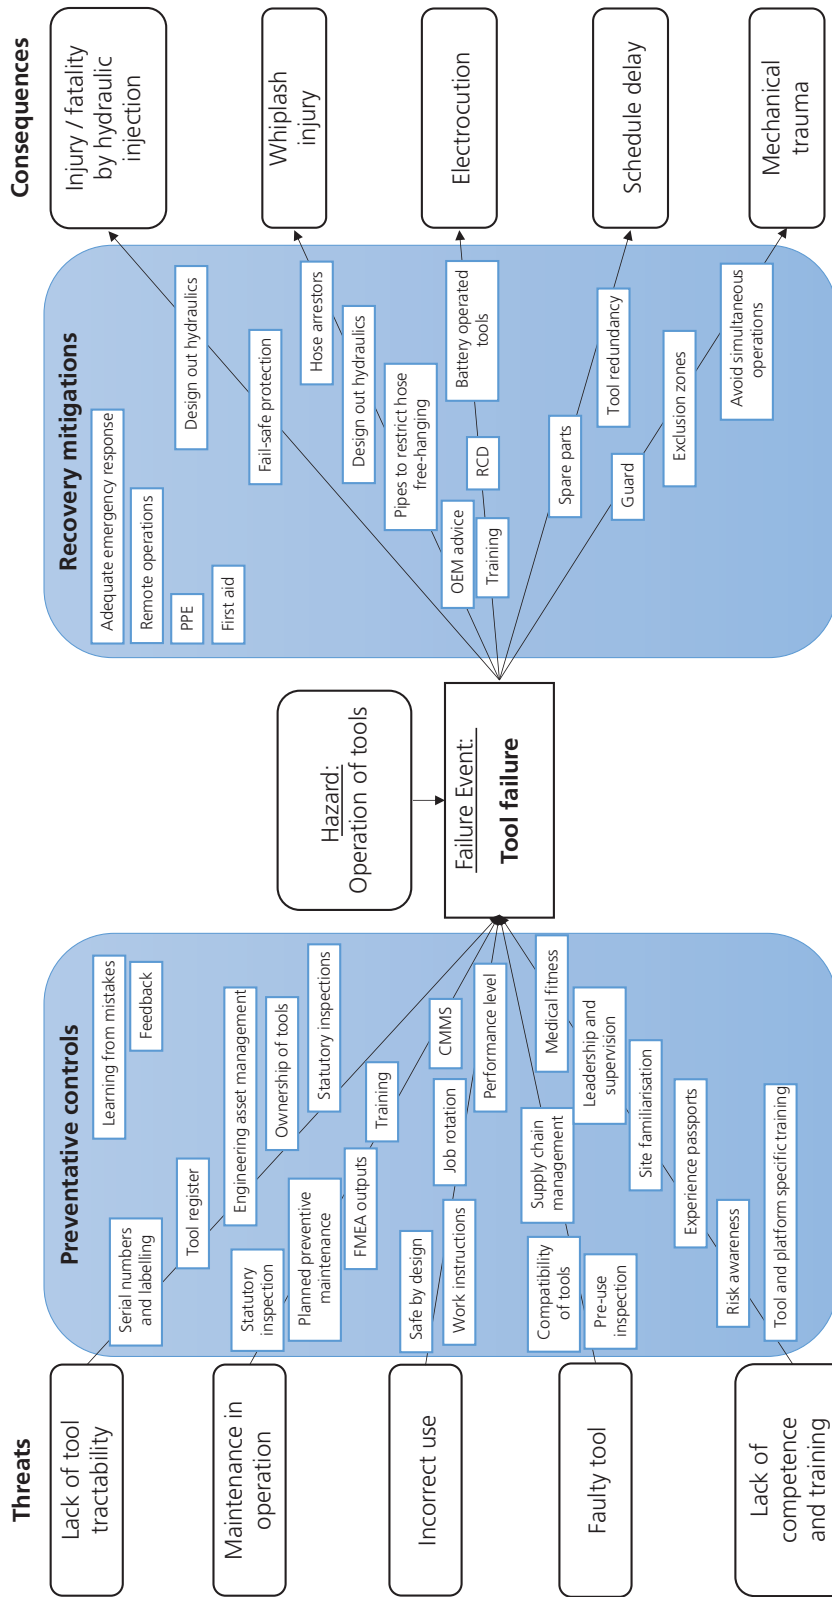

Figure A.5: Tool failure in operation bow tie (1/2)

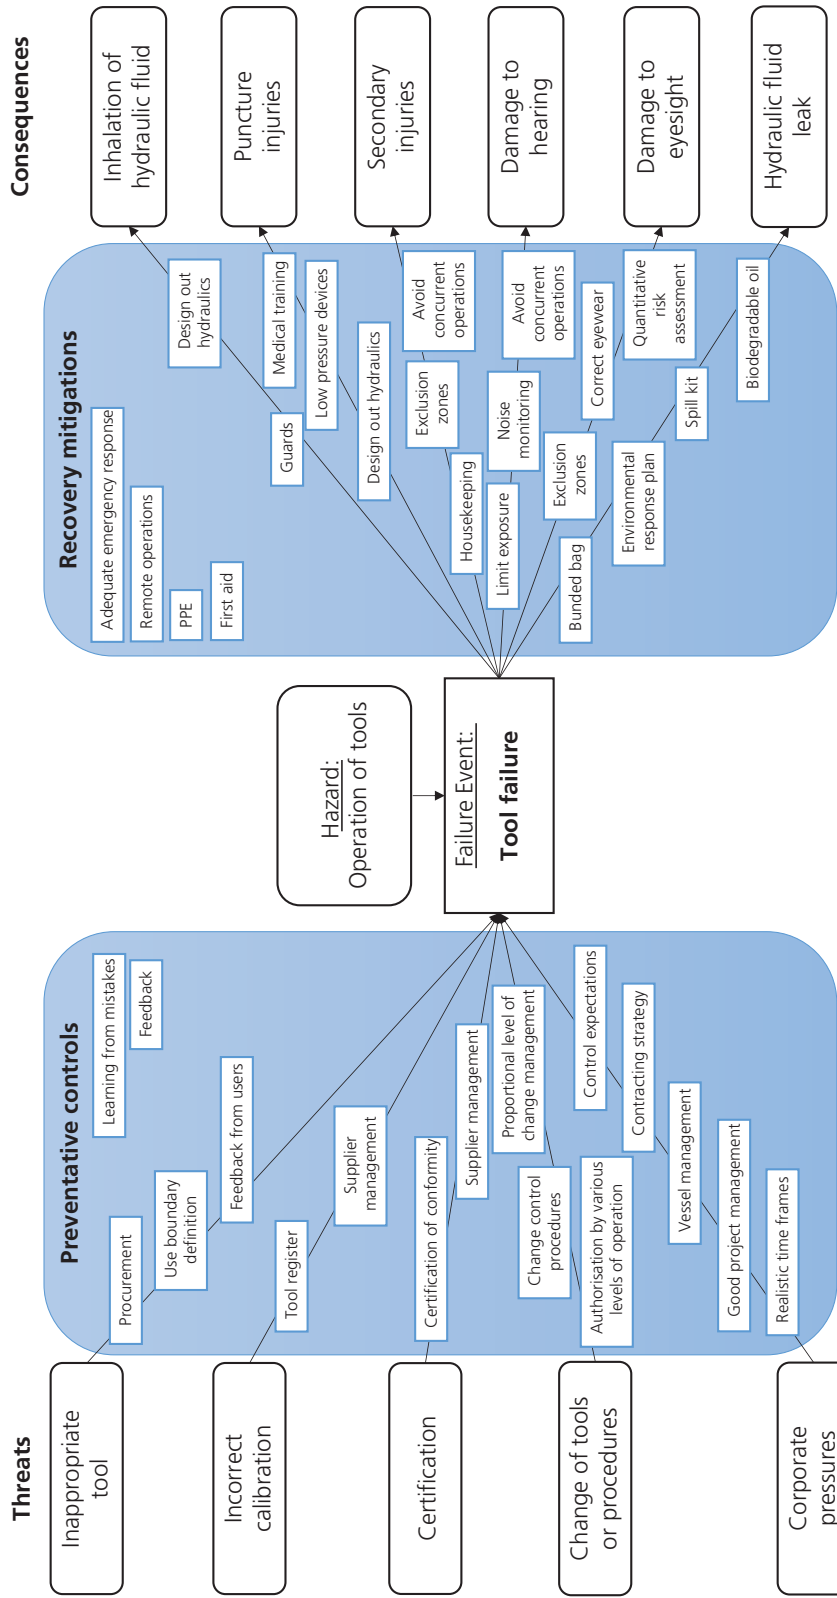

Figure A.6: Tool failure in operation bow tie (2/2)

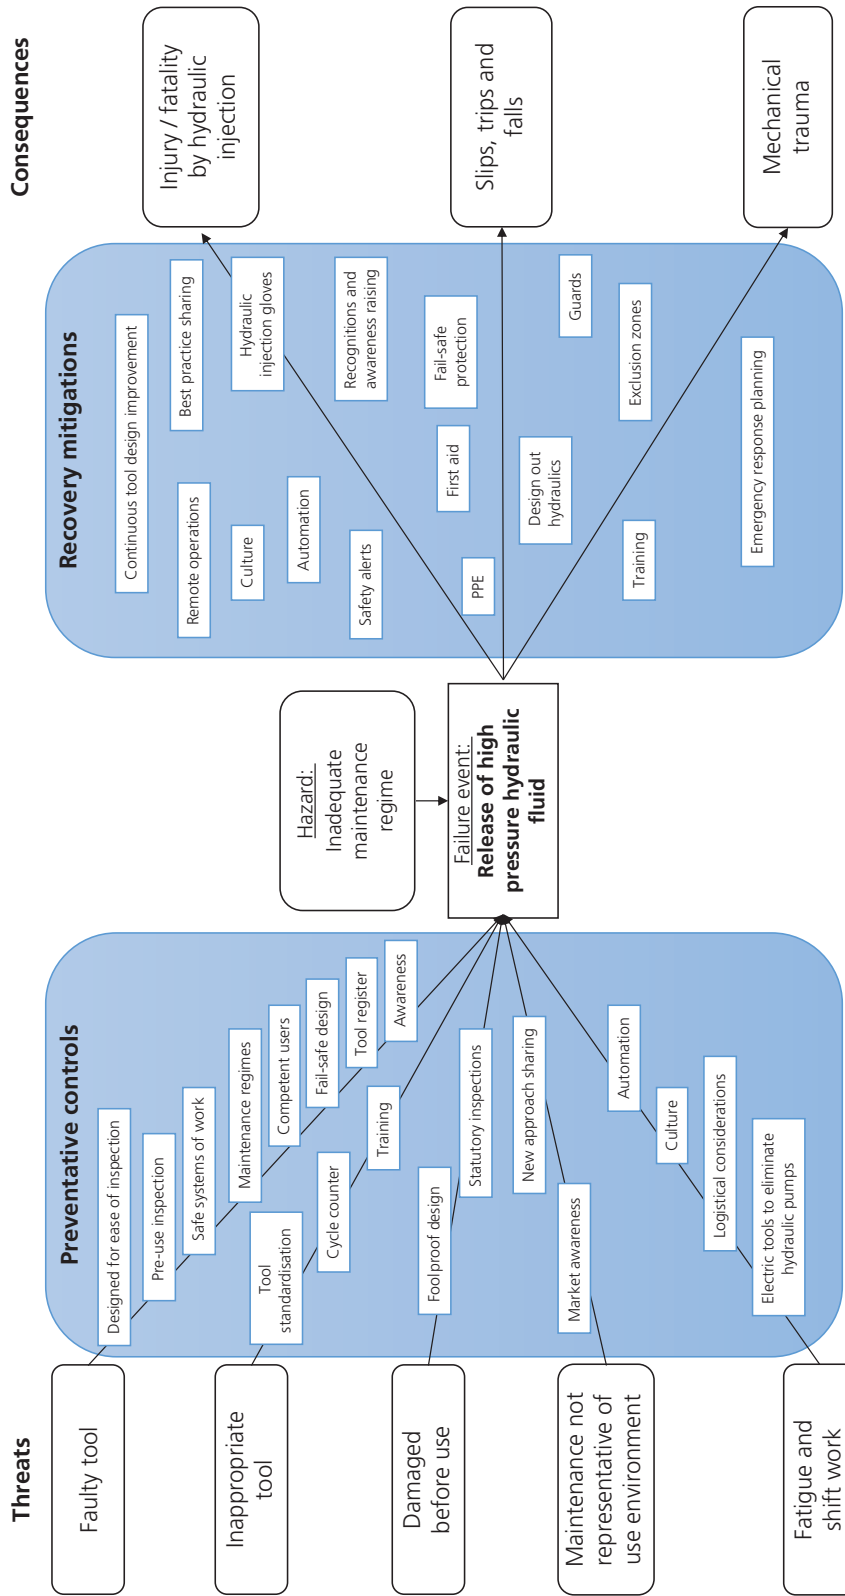

Figure A.7: Release of high-pressure hydraulic fluid bow tie (1/2)

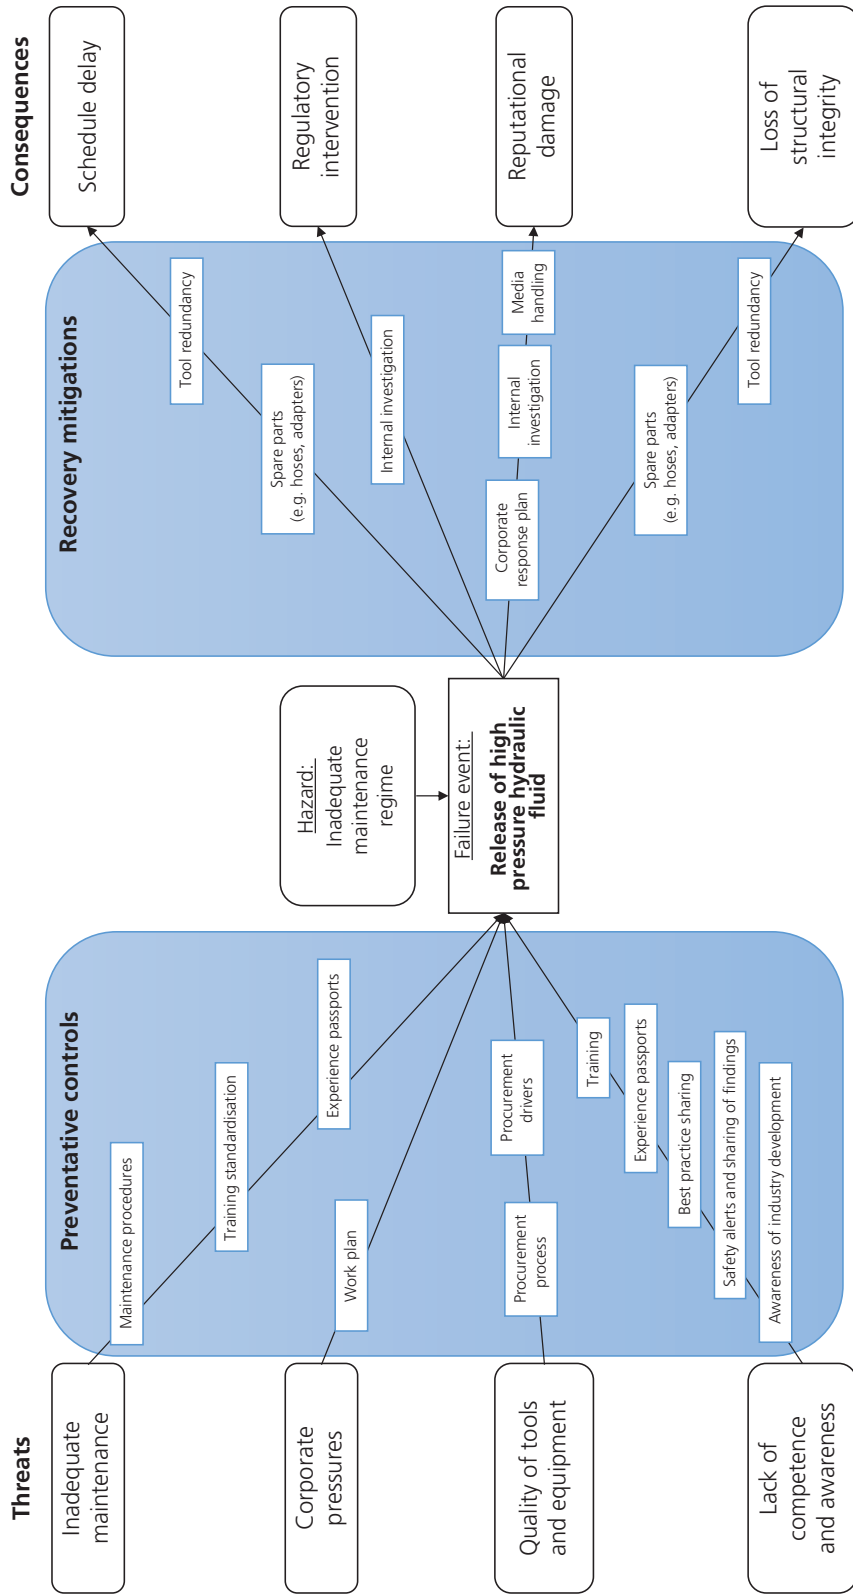

Figure A.8: Release of high-pressure hydraulic fluid bow tie (2/2)

### A.2.2.2 Analysis and findings

The bow tie diagrams clearly illustrate the group discussion areas for each failure event. The key findings for each hazard and failure event, as well as general findings, include the following:

- **Hazard:** Handling (storage, transportation and handling). **Failure event:** Tool failure.
- Most of the bolt torqueing and tensioning tool failures in storage, transportation and handling discussed can be prevented by developing and applying procedures, performing equipment inspections and maintenance, ensuring that technicians are trained and competent, and have access to the right tools for the job.
- Tool damage could be reduced by removing sensitive components (e.g. gauges and sensors) during transportation and using markings, such as 'This way up' on bags or 'Hold here' on tools, during storage, transportation and handling. Markings could also help improve H&S by ensuring that equipment is handled correctly, reducing probability of injuries and dropped equipment.
- Workshop participants felt that bags used for tool storage, transportation and handling could be improved to prevent tool and environmental damage (e.g. use of banded bags to capture hydraulic fluid leaks).
- **Hazard:** Operation of the tools. **Failure event:** Tool failure.
- Guards, exclusion zones and avoidance of simultaneous operations were some of the most common mitigations suggested by workshop participants for various types of H&S consequences.
- No consensus was reached on whether use of torqueing and tensioning tools can lead to damage to hearing, with workshop participants expressing contradictory opinions, which could be as the result of different tools being used.
- **Hazard:** Inadequate maintenance regime. **Failure event:** Release of high-pressure hydraulic fluid.
- Hydraulic injection can lead to life-changing and potentially fatal consequences. Whilst numerous preventive control and recovery mitigations were suggested, from procedural to changing tool design, hydraulic injection resistant gloves were seen by the workshop participants as one of the easiest to implement solutions to prevent hydraulic injection injuries.
- Improving recognition and awareness of hydraulic fluid hazards and potential consequence of these, as well as best practice sharing, is an easy and inexpensive way of educating and potentially preventing hydraulic injections.
- General findings.
- Storing spare parts and/or tools for bolt torqueing and tensioning on vessels or permanently on WTGs was suggested in all groups as means to mitigate most non-H&S related consequences associated with the transport of tools.
- Substitution of hydraulic tools for electric tools can eliminate hydraulic fluid and hose whiplash injuries, as well as reduce the probability of other types of H&S (e.g. slips, trips and falls, puncture injuries) and environmental consequences. If battery-based solutions are used, these would also eliminate the requirement for a transportable power supply.
- Corporate pressures at different levels was identified by workshop participants as a less visible yet still present threat that needs to be managed by having realistic time frames, good project management and controlled expectations based on evidence and historical data.

**A.2.2.3 Recommendations and outputs**

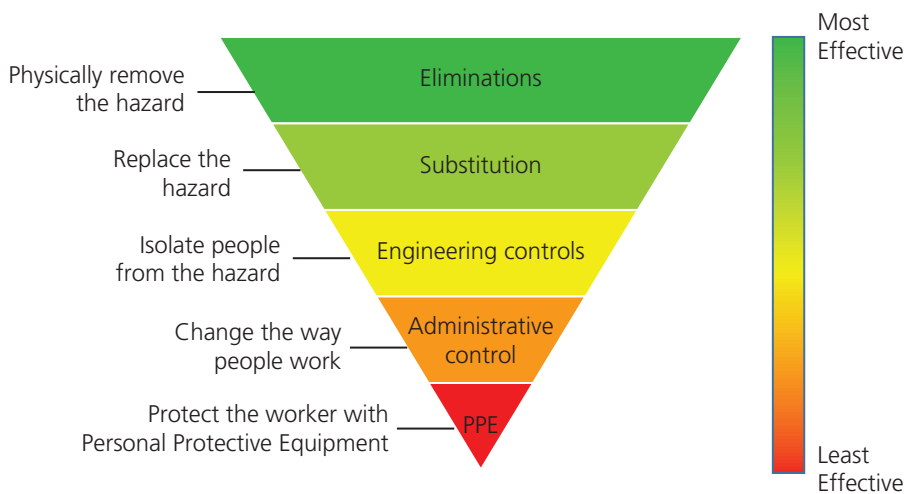

The following thoughts, considerations and recommendations were developed during Exercise 2. The refined report recommendations are shown in the Executive Summary in Section 1.

- It is recommended that the G+ create an information sharing mechanism to facilitate the distribution of best practice, learnings from mistakes and feedback from technicians with respect to bolt tensioning and torqueing-related activities and tools.
- As an independent and impartial group, the G+ could perform a cost-benefit analysis of permanently storing spare parts and/or tools for bolt tensioning and torqueing on WTG (i.e. the benefit of being able to perform work versus additional inspections and maintenance offshore).

**A.3 WORKSHOP EXERCISE 3: HIERARCHY OF CONTROLS**

**A.3.1 Purpose**

The purpose of this exercise was to apply the top two levels of the hierarchy of controls (elimination and substitution), as shown in Figure A9, to the hazards identified in Exercise 1. Each group chose the significant hazards from Exercise 1 and applied the hierarchy of control to each, starting with elimination and followed by substitution.

**Figure A.9: Hierarchy of controls by IOSH**

**A.3.2 Outputs**

**A.3.2.1 Evidence**

Some hazards have been identified in multiple activities. These activities are shown in Table A.4 and colour-coded, as shown here:

Use of tools (operation of the tools)	
Tools' maintenance	
Storage and transportation and handling	

It should be noted that there may be overlap and/or duplication in the eliminations and substitutions for each activity stated in Table A.4. This is since similar eliminations and substitutions have been recommended, by each of the exercise groups, for several hazards. Similarly, there may be information captured in one activity that may be applicable to others. These factors have been highlighted in the recommendations provided from this exercise.

**Table A.4: Hierarchy of controls**

Hazard	Activity	Elimination	Substitution	Additional comments
Manual handling and ergonomics	Use of tools	Automation and use of robotics Eliminate flanged connections QC of bolted connection at installation to reduce/remove maintenance checks Ultrasonic preload measurement (and other remote checks)	Replace hydraulic tools for electric alternatives Design bolts and tools to allow the use of mechanical lifting aids Design of platform levels Use of reaction washers Read G+ good practice guidelines for manual handling Use of smaller tools (e.g. lightweight pumps)	Automation could include self-installing turbines Increasing the size and weight of bolts/tools may actually be beneficial to safety as the requirement for mechanical lifting aids becomes a necessity rather than a luxury Consider WTG locations as 'place of work' during design process
	Storage and transportation	Design changes – WTG	Improved collaboration between foundation and WTG OEM designs Tool/equipment securing during transportation and/or storage Pre-installation of bolts Keep equipment on-site/WTG for the whole design life	Design changes could include TP-less designs, or a change in connection design – thus reducing the requirement for vast tool/bolt storage Improved collaboration would ensure technician safety is considered in the installation and O&M processes

**Table A.4: Hierarchy of controls (continued)**

Hazard	Activity	Elimination	Substitution	Additional comments
Competency and training	Use of tools	<ul style="list-style-type: none"> <li>– Automation and use of robotics</li> <li>– Foolproof design (inherently safe)</li> </ul>	<ul style="list-style-type: none"> <li>– OEM handover training in specific use of tools and processes</li> <li>– Tracking of technician competency and match competency to specific jobs using a colour coded system</li> <li>– Task-specific training is required to ensure adequate knowledge of tasks prior to operational intervention</li> <li>– Use of experience passports</li> </ul>	<ul style="list-style-type: none"> <li>– There is learning to be gained from other industries – such as the use of colour coded systems to ensure personnel training/ competency is matched to specific tasks</li> <li>– Task-specific training should be organised by the appropriate body and all training programmes should be accredited and audited</li> <li>– Feedback of incident data (to the G+ and the wider industry) is required to prioritise training and address key issues</li> <li>– Foolproofing design – designing tools so they are generic to the application (bolt size/type) would reduce tool misuse</li> </ul>

Noise and vibration	Use of tools	<ul style="list-style-type: none"> <li>– Automation and robotics</li> </ul>	<ul style="list-style-type: none"> <li>– Use of electric tools</li> <li>– Ensure sufficient maintenance of tools</li> <li>– Benchmarking/ prioritising selection of tools (not just based on cost)</li> <li>– Use of bolt tensioning over torqueing</li> <li>– Consultation and sharing of data/ information</li> </ul>	<ul style="list-style-type: none"> <li>– There is some uncertainty around the levels of noise present when using hydraulic tools</li> </ul>
Lack of ownership of risk	Storage and transportation	<ul style="list-style-type: none"> <li>– Improved risk transfer</li> <li>– Design tools that cannot be used after a specified number of cycles/ uses</li> </ul>		<ul style="list-style-type: none"> <li>– Improved risk transfer could, for example, mean placing more emphasis on tool providers for ensuring safe working practices</li> </ul>

#### A.3.2.2 Analysis and findings

Across all the activities and hazards discussed, four key approaches to hierarchy of controls were noted:

- Remove/reduce the need for hydraulic torqueing and tensioning activity by:
  - Eliminating flanged connections from design.
  - Ensuring QC of bolted connections at installation to reduce requirement for return visits or checking as part of an ongoing maintenance regime.
  - Using ultrasonic preload measurement (or other remote checks).
- Automate processes and embrace the use of robotics, including:
  - Use of smart bolts for remote maintenance checks.
  - Use of reaction washers.
  - Use of drones for tool/equipment transfer.
- Improve training and competency tracking; specific recommendations include:
  - Task-specific training to ensure competency in an operational environment.
  - Training specific to offshore activity processes and selection/use of tools should be provided during OEM handover.
  - Tracking of competency, by using a passport/colour-coding methodology, could be implemented to match technician competency to specific tasks.

- Implement design changes, such as:
  - Tool-specific design changes, such as integrating tool use/cycle counters and bespoke lifting bags, could reduce the likelihood of tool failure. Hydraulic tools could also be substituted for electric alternatives.
  - Turbine-specific design changes such as improving platform designs, use of anchor points for assisted lifting and considering WTGs as 'places of work' during design could eliminate ergonomic hazards.

There is a consensus that designing to eliminate the need for hydraulic tooling would be beneficial to the industry. However, this would not eliminate all associated hazards as flanged connections are used throughout the already existing offshore fleet. Therefore, substituting hydraulic tooling for electric alternatives could be a feasible design change, as would implementing more anchor points and safety features on the tools and in the working environment (the WTG) already in place.

It should be noted that the elimination or substitution of certain hazards can introduce new hazards to specific activities. An example of this would be the substitution of hydraulic tooling for electric alternatives, which would introduce the associated hazard of electrocution. These new hazards should always be identified and considered when evaluating the impact of the changes recorded in this section.

#### *A.3.2.3 Recommendations and outputs*

The following thoughts, considerations and recommendations were developed during Exercise 3. The refined report recommendations are shown in the Executive summary in Section 1.

- Task-specific training could be beneficial to ensure competency during operations and relevant training programmes should be organised, accredited and audited by the appropriate body. The G+ could influence the content of this training by collecting and comparing safety data throughout the industry to help identify areas/activities to focus on.
- Relevant learning could be gained from other industries regarding competency tracking and training practices. The G+ could commission a study into these practices from other industries and, in collaboration with Owners and Operators, produce good practice guidelines on this topic for the offshore wind industry.
- WTGs and TPs do not seem to be wholly considered as 'places of work' during the design process. Several ergonomic hazards were identified that could be designed out of future WTGs and TPs. It could be beneficial to facilitate the engagement of OEMs, Owners & Operators and technicians to share feedback from issues/accidents attributed to these design features.
- Tracking tool use, maintenance and calibration was identified as an issue relating to tool failure. Emphasising the need for these aspects to be incorporated into future tool designs would be of benefit for the industry. This could be realised by a body, such as the G+, gathering insight from the industry and publishing a set of recommended requirements specific to hydraulic tooling.

## **ANNEX B PRESENTATIONS**

### **B.1 PRESENTATION 1 – ARUP – TYPICAL BOLTED CONNECTIONS**

#### **B.1.1 Executive summary**

This presentation was provided to highlight the design drivers behind monopile (MP) to TP bolted flange considerations and the requirement for re-tensioning in service.

The presentation contains the following:

- An overview of typical MP-TP bolted flange arrangements and a description of why they have become widely used, as opposed to other MP-TP connection options, e.g. grouted connections.
- A description of the in-service issues that drive the requirement for re-tensioning in service and experience from other more established industries, e.g. bridges and antenna structures, to highlight best practice.
- A summary of products available that may enable more accurate measurement of bolt preload or reduce the maintenance overhead.

A key message is that the requirement for through-life inspection and re-tensioning of preloaded bolts is consistent with a range of other, more established industries. For these industries, there are examples of where the frequency and nature of the maintenance regime has evolved based on in-service experience.

# G+ Safe by Design Workshop: Hydraulic Torqueing/Tensioning Systems

## Typical Bolted Connections

George Walker | Arup  
 george.walker@arup.com  
 +44 20 7755 2502

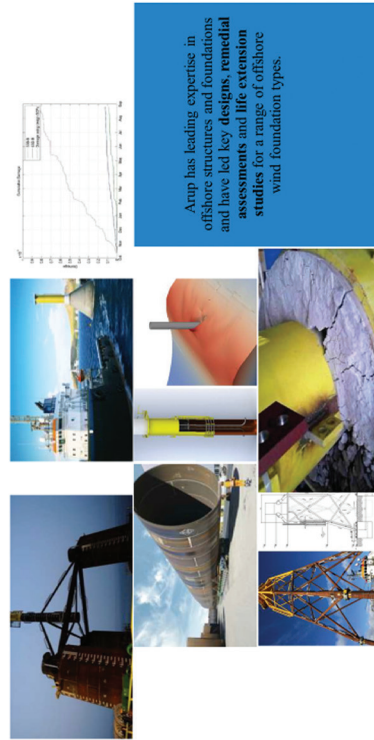

1

### Aim and Agenda

*Summary of the design drivers behind MP-TP bolted flange connections, and the need for re-tensioning.*

1. Overview of MP-TP bolted flange connections
2. Why are bolted flange connections required?
3. What drives the requirement for re-tensioning?
4. Experience from other industries
5. Available technology

ARUP 2

Arup has leading expertise in offshore structures and foundations and have led key designs, remedial assessments and life extension studies for a range of offshore wind foundation types.

ARUP 3

### Typical Bolted Flange Connections

Key features:

- HSBG bolts protected from corrosion by grout filled skirt.
- High tolerance and machined interface surface to reduce prying action.
- Thick flange plates to reduce local bending.
- Preload to 70-75% of ultimate strength to ensure adequate cyclic performance.

ARUP 4

## Requirement for Bolted Flange Connections

Grouted TP-MP Connection - Residual Design

CONTRAST CONNECTION BETWEEN THE TENSIONING JACK AND THE RECEIVING (GMP)

High-strength grouted TP-MP connections were the original choice for European wind farms.

Advantages:

- Proven technology\*
- Enables relaxed tolerance for verticality.
- No special corrosion protection measures. However, the connection design type suffered settlement under cyclic loading. This resulted in development of shear key and conical solutions, but in-service settlement remained an issue.

## Requirement for Bolted Flange Connections

Bolted Flange Connection

BS 7608: The Effect of Bolt Preload on Fatigue Stress

Bolted flange connections have become the preferred TP-MP connection choice, despite disadvantages compared to a grouted solution:

- High tolerance required for verticality.
  - Issues with hammering on flange during installation.
  - High corrosion risk associated with HSEFG bolts.
  - Maintenance requirement.
- Preload to 70-75% of ultimate strength to improve adequate cyclic performance. This has the equivalent effect as a significantly higher fatigue detail class.

ARUP 5

ARUP 6

## Re-tensioning Requirements

### NON ROTATIONAL LOOSENING

Causes of HSEFG Loosening  
([www.windpowermaintenance.com](http://www.windpowermaintenance.com))

Bolt inspection and re-tensioning may be required due to a range of potential in-service issues, for example:

- Surface coating/gasket creep.
- Joint creep.
- Yielding under load.
- Slippage of HSEFG nut or incorrect initial tension applied.
- Differential thermal expansion.
- Excessive vibration.

## Experience from Other Industries

Van Bovensoordbrug Bridge, Holland

### HSEFG Bolts in Bridges

- A key issue is demonstrating adequate preload is applied, pretensioners help solve this problem.
- Simpler methods are used widely but have implications on quality, e.g. torque-wrench angle method which is reliant on the geometry of the thread.
- Corrosion protection and inspection essential, e.g. through coating and inspection regime.
- Conservatism in the bridge engineering market leads to high redundancy, which can reduce the requirement for retightening through the service life.

ARUP 7

ARUP 8

## Experience from Other Industries

High Roller Wheel, Las Vegas

- HSEB Bolts in Slender Structures  
Frequent inspection and maintenance requirements, particularly at early stages following construction.
- As more experience is gained in an industry, the maintenance requirements can evolve.
- Where possible (e.g. radio mast trusses), alternatives to HSEB are often taken as the preferred choice.

ARUP 9

## Conclusions

- Bolted flange MP-TP connections are the preferred choice for offshore wind due to issues associated with grouted solutions.
- A range of mechanisms can cause loss of preload, which is essential for fatigue performance, leading to the maintenance requirement.
- This is consistent with experience in a range of other industries. Preloaded bolts have stringent inspection requirements, particularly to monitor corrosion.
- Products are available to more accurately measure bolt pre-load which may reduce inspection/maintenance overhead. In-service experience is more typically relied upon to inform an appropriate maintenance regime.

ARUP 11

## Available Technology

NORO-LOCK

- Products are available to enable more accurate measurement of bolt preload and to improve resistance to slip.
- These products aim to reduce maintenance and inspection requirements.
- However, conservatism in the construction market leads to high redundancy and reluctance to adopt novel products for monitoring preload.

- 1. RotaBolt
- 2. RotaBolt Washer
- 3. Nut
- 4. Bolt

Resin Injection Bolts (Emsco, Annex 2)

## **B.2 PRESENTATION 2 – E.ON CLIMATE & RENEWABLES GMBH – MP/TP BOLTING OPERATIONS**

### **B.2.1 Executive summary**

The presentation was provided to inform the audience of the two methods of bolt tightening and the risks associated with each. Its main aim was to facilitate the further discussions on the hazards and risks of bolting, especially on the MP-TP flange using M72 bolts. Therefore, it should be noted that the slides are filled with useful pictures of what not to do!

The presentation was focused on three main areas:

- A section of the presentation was dedicated to the logistical hazards and problems associated with offshore bolting works.
- The main body of the presentation explained the many hazards associated with the process.
- The final section looked at the different tool failures that have occurred during E.ON's many bolting activities.

Associated risks were also highlighted to allow the participants of the HAZID workshop exercises to form holistic judgements of the process and not simply focus on the risks at the point of work.

# MP/TP Bolting Operations

Challenges related to torqueing and tensioning M72 bolts

## Content of myPresentation

1. Brief overview of an MP-TP Connection and the Logistical problems
2. Torque vs Tension and the Risks with associated with both
3. Risks in detail
4. E.ON's tool failures experiences
5. Questions

### Monopile – Transition Piece (MP-TP) Connection

- Bolted Monopile to Transition Piece Connection, is the main structural load path
- 90-120No. M72 Bolts per Connection
- Bolt pre-tension is the critical parameter that dictates the fatigue life of the bolts

### Monopile – Transition Piece (MP-TP) Connection

- Why is it a logistical nightmare?
- Getting there with all the equipment:
  - Installation
  - Inspections or re-works

### Monopile – Transition Piece (MP-TP) Connection

- Why is it a logistical nightmare?
- Below air tight deck? (older are more often than newer TPs)
- Internal space for lifting?

### Torque and Tension

- Different mechanics - Different controlling methods – Different risks – Similar Outcome Expected
- Use often determined more by external Non-HSSE factors (regulations, historical, tool availability/cost, etc.)

6

### Torque and Tension - Issues

	Torque	Tension
Weight of bolts and tools manual handling and lifting aids	✓	✓
Hose and cable management	✓	✓
Electrical cables / air hoses/ hydraulic hoses	✓	✓
Hydraulic tools high pressure	✓	✓
Moving parts and pinch points	✓	✓
Torqueing with high moments	✓	✓
Tool storage & maintenance height of flange and working on the underside	✓	✓

### Weight of bolts

- M72 bolt with nuts and washers → 17 kg to 20 kg each
- ~ 2,000 kg for one complete flange
- Lifting 1 Bolt manually might be acceptable, but up to 120 should be avoided
- Bolts could slip out of hands due to fatigue

Changing all bolts in an opening. WTF is not common, but has happened with the E.ON

7

### Hose & cable management

- 110 V / 230 V electrical cables
- Hydraulic hoses
- Remote cable
- Lifting ropes
- Very messy and dangerous

### Weight of tools

- Typical torque and tensioning tools
- Weight starts at 35 kg
- Torque gun setup at the bottom right weighs 75 kg
- Tools can be broken down into lighter components which is time consuming
- For tensioning 10 – 12 tools are used at the same time
- Having to move the tool manually many times should be avoided

### High pressure hoses

- Torquing up to 700 bar
- Tensioning up to 2500 bar
- Hoses are easily damaged if not banded after
- Couplings wear over time and will fail eventually

### Pinch points and moving parts

- Torquing only as tensioning is within a closed tool
- Up to 30.000 Nm reacting on single points in worst cases
- Needs a solution to be hands free and back-up wrench secured differently

11  
9

15  
12

### Storage & transportation

- Tools are transported in lifting bags
- All in one bag thrown together
- Heavy tools resting on hoses
- Steel on steel resting against each other

### Maintenance of tools

- Tools are working towards their limits as being used 24/7
- High pressure involved
- Frequent use of the couplings as handles, due to lack of other obvious easy lifting points
- Vague maintenance time interval specifications from the manufacturers
- "Tools should be regularly maintained" (???)
- Meaning Contractors define exact schedule

### Torque Tool Failure

- Failure of the hydraulic hose coupling
- No one injured, hydraulic oil mist – but a very shaken operator
- Retaining plates sheared
- RCA found it was a manufacturing fault, exacerbated by poor handling and maintenance

### Tension Tool Failure

Remained connected!

Threaded connection to tension head

Purple part was a single piece casting

0.1 - 0.2 mm (rounding 2.5mm deep threads)

Insertion face

0.1 - 0.2 mm (rounding 2.5mm deep threads)

Insertion face

**Thank you**  
**Any questions?**

**Other risks and hazards**

- Confined Spaces
- Working at heights
- Lifting and suspended loads
- Electrics (HV/LV)
- Housekeeping
- Offshore environment
